1 Introduction

In this experiment, k-means clustering was applied to the UCI heart disease data set¹, with the factors being the distance formula used and the number of clusters formed. The three levels for the distance formula used were Euclidean distance, Cosine distance, and Jaccard distance. The three levels for the number of clusters were 2, 3, and 5. The response variable of interest is the resulting sum squared error of the clusters.

2 Design

The design of the experiment was a completely randomized design. To achieve this, every possible combination of the factors was run in random order, with each combination being run twice. The initial starting points for each cluster was also initialized randomly. “Environmental Error” is introduced by randomly choosing data points to train on and data points to test against.

3 Procedure and Data Collection

To collect data, k-means clustering was performed using the Python library nltk². The data for the k-means clustering itself was taken from the UCI heart disease data set and each point contained 14 used attributes, which are as follows:

1. Age
2. Sex
3. Chest Pain Type
4. Resting Blood Pressure
5. Cholesterol Level
6. Fasting Blood Sugar > 120 mg/dl
7. Resting ECG Results (normal, ST-T wave abnormality, left ventricular hypertrophy)
8. Maximum heart rate achieved
9. Exercise induced Angina
10. ST Depression Induced by Exercise Relative to Rest
11. Slope of Peak Exercise ST Segment (up-sloping, flat, down-sloping)

5 Conclusion

The ANOVA table can be found in Table 1. Using $\alpha = 0.05$, the different combinations of factors was significant, as Prob > F < .0001, which is less than 0.05. Using the effect tests table, found in Table 2,

several things can be concluded. There is no interaction between the Distance Metric and the Number of Clusters, as $\text{Prob} > F = 0.1711$, which is greater than 0.05. The Distance Metric was also not significant as $\text{Prob} > F = .3757$, which is greater than 0.05. The number of clusters, however, was significant, as $\text{Prob} > F < .0001$, which is less than 0.05. Each number of clusters was statistically distinct and having two clusters produced the most accurate predictor, as shown in Table 4 and Table 3. Tukey’s test was performed on the number of clusters instead of a regression as the number of clusters is discrete, and not continuous.
